

A Living Evidence Synthesis on Variants of Concern and COVID-19 Vaccine Effectiveness

Initial Results for Outcomes related to Post-Acute Sequelae of SARS-CoV-2 Infection (PASC)

(Report #2, Version 2.8: March 30, 2023)

Introduction

As part of the CIHR-funded project "A Living Evidence Synthesis on Variants of Concern and COVID-19 Vaccine Effectiveness", this report provides initial results on vaccine effectiveness against outcomes related to post-acute sequelae of SARS-CoV-2 infection (PASC). Results are reported from preprints released as of March 8, 2023, and published literature released as of January 12, 2023.

This report is the second report in our living evidence synthesis. The report provides an update of the previous report regarding the effectiveness of the vaccine on PASC outcomes. In this update, we included **three new studies** that reported vaccine effectiveness on the following PASC outcomes: overall PASC prevalence, respiratory, fatigue and exhaustion, nervous system and cognitive functioning, symptoms, and conditions. No new studies provided information on Omicron subvariants.

Methodology

A detailed methodology for the literature search and eligibility criteria is available in the protocol, which is registered on PROSPERO (<u>CRD42022359790</u>) and the Open Science Framework (https://osf.io/gacw4/).

In this report, vaccine effectiveness results are provided in tables separated by outcome. When a single study was available for an outcome, the vaccine effectiveness was calculated from the most adjusted estimate of effect provided in that study's results. If more than one study was available, then the vaccine effectiveness was calculated for each study and the range was given. All vaccine effectiveness estimates were rounded to the nearest whole number. Study results that were not able to be synthesized in the vaccine effectiveness tables are provided in Appendix 2.

We considered the overall prevalence of PASC, i.e. the presence of one or more symptoms at least 12 weeks after COVID-19 diagnosis [1] as a non-specific outcome. We considered specific PASC outcomes in the following outcome domains:

- Respiratory functioning, symptoms and conditions
- Fatigue or exhaustion
- Pain
- Nervous system functioning, symptoms and conditions
- Cognitive functioning, symptoms and conditions
- Mental functioning, symptoms and conditions
- Cardiovascular functioning, symptoms and conditions

These outcome domains were selected from the core outcome set for PASC [2], based on their relatively higher prevalence from systematic reviews [1, 3–9]. A complete list of all outcomes within these domains is provided in Appendix 3. The overall number of PASC symptoms, quality of life, overall functional impairment (ability to perform daily living activities) and ability to work at least 12 weeks after COVID-19 diagnosis were also outcomes of interest.

For each study, a risk of bias assessment was conducted using a modified version of the ROBINS-I tool [10], which was adapted specifically for studies on vaccine effectiveness against PASC outcomes. This modified tool is provided in Appendix 5. An overall risk of bias judgement was given for each study, ranging from Low, Moderate, Serious, or Critical. In the synthesis tables, the risk of bias judgement is colour-coded as follows:

Low risk of bias	Moderate risk of bias	Serious risk of bias	Critical risk of bias

Studies with three Serious domains were given a Serious overall risk of bias judgement, rather than Critical (as was done in the original living review [11]). Since we are in the early stages of collecting evidence on vaccination and PASC, it is helpful to provide insight into the domains that are rated as Serious.

Study characteristics, such as the study design, time period, and population, are provided in Appendix 4.

Overall Summary of Results

Overall, 14 studies that examine PASC outcomes have been included: 19 published studies and 5 preprints. For an overview of the study selection process, see Appendix 1.

We present data for the following outcomes: overall prevalence of PASC (Table 1.1-1.6); respiratory (Table 2.1-2.6); fatigue or exhaustion (Table 3.1-3.5); pain (Table 4.1-4.5); nervous system (Table 5.1-5.5); cognitive (Table 6.1-6.2); mental (Table 7.1-7.5); and cardiovascular functioning, symptoms and conditions (Table 8.1-8.4). We also present data for the overall number of PASC symptoms (Table 9).

None of the included studies provided data on the association between vaccination and quality of life or ability to work. For overall functional impairment, two studies reported "activity-limiting PASC" as an outcome (defined by the authors as PASC that limits daily activities) [12, 13], which we present in Table 1.1 and 1.6.

Across all included studies, the following vaccine types and brands were reported: mRNA, inactivated viral vaccine, viral vector vaccine, ChAdOx1 (AstraZeneca), BNT162b2 (Pfizer-BioNTech), mRNA-1273 (Moderna), Ad26.COV2.S (Janssen), and CoronaVac.

None of the included studies were conducted in Canada; five were done in the USA, two in the UK, two in Switzerland, and the remaining six studies were done in Denmark, Norway, Indonesia, Brazil, and South Africa, respectively.

Omicron results are highlighted in yellow in this report, since it is currently the dominant variant of concern in circulation.

1. Overall prevalence of PASC

Table 1.1. Vaccine effectiveness against the development of PASC among individuals infected with SARS-CoV-2 (Alpha, Beta, Gamma, Delta, or Omicron)

Outcome (and vaccine)	Number of doses	Time since infection	Vaccinated pre-or post-infection	Effectiveness (95% CI)	Comparator	Dominant variant during infection period	References
PASC (any s	symptom/sed	quelae)				-	
	2	12+ weeks	Pre-infection	53% (30, 68)	Unvaccinated	wildtype, Alpha, Delta	[12]*
	2	6 months	Pre-infection	0% (-6, 5) to 15% (11, 18)	Unvaccinated	Delta; Alpha, Delta	[14, 15]
	2	8-12 months	Pre-infection	22% (10, 32)	Unvaccinated	wildtype, Alpha	[16]
mRNA	1 or 2	6 months	Pre-infection	47% (-6, 78)	Unvaccinated and infected with wild-type	Delta	[17]
	1 or 2	6 months	Pre-infection	51% (13, 74)	Unvaccinated and infected with wild-type	Omicron	[17]
	3	6 months	Pre-infection	-84% (-1884, 92)	Unvaccinated and infected with wild-type	Delta	[17]
	3	6 months	Pre-infection	70% (30, 90)	Unvaccinated and infected with wild-type	Omicron	[17]
Inactivated viral vaccine	2	3 months	Pre-infection	26% (-7, 50)	1 dose or unvaccinated	Alpha, Beta, Delta	[18]
mRNA or viral vector vaccine	2 mRNA or 1 viral vector	4-10 months	Pre-infection	31% (18, 41)	Unvaccinated	Delta, <mark>Omicron</mark>	[19]
ChAdOx1	2	12+ weeks	Pre-infection	29% (12, 43)	Unvaccinated	wildtype, Alpha, Delta	[12]*
BNT or Janssen	2 BNT or 1 Janssen	6 months	Pre-infection	-3% (-25, 15)	Unvaccinated	Beta, Delta, Omicron	[20]
CoronaVac ChAdOx1 BNT or	2	180 days	Pre-infection	-17% (-76, 21)	Unvaccinated	Gamma, Delta, <mark>Omicron</mark>	[21]
Janssen	3	180 days	Pre-infection	37% (-2, 61)	Unvaccinated	Gamma, Delta, <mark>Omicron</mark>	[21]

	4	180 days	Pre-infection	95% (81, 99)	Unvaccinated	Gamma, Delta, <mark>Omicron</mark>	[21]				
Activity-limiti	Activity-limiting PASC										
mRNA	2	12+ weeks	Pre-infection	55% (24, 74)	Unvaccinated	wildtype, Alpha, Delta	[12]*				
ChAdOx1	2	12+ weeks	Pre-infection	32% (9, 49)	Unvaccinated	wildtype, Alpha, Delta	[12]*				

^{*}Estimate is from the analysis that only examined the subset of participants with confirmed vaccination status. Almost all double-vaccinated individuals were infected during Delta dominance, while almost all unvaccinated individuals were infected before Delta dominance (with Alpha or wild-type).

9. Number of symptoms

Table 9. Vaccination and number of PASC symptoms among individuals infected with SARS-CoV-2 (Alpha, Delta, or Omicron).

Vaccine type	Number of doses	Time since infection	Vaccinated pre-or post- infection	Key findings	Comparator	Dominant variant during infection period	References
mRNA or ChAdOx1	2	9 months	Post- infection	A second ChAdOx1 or mRNA dose post-infection was not associated with a change in the odds of experiencing at least 3 of 21 PASC symptoms (aOR 0.931, 95%CI 0.852-1.016, p=0.11) or at least 5 of 21 PASC symptoms (aOR 0.982, 95%CI 0.886-1.088, p=0.73).	Same individuals before vaccination	Alpha, Delta	[13]

^{**}Immunocompromised was defined as "a history of organ transplantation, advanced kidney disease (an estimated glomerular filtration rate of less than 15 ml/min/1.73 m2 or end-stage renal disease), cancer, HIV or conditions with prescriptions of more than 30-day use of corticosteroids or immunosuppressants, including systemic lupus erythematosus and rheumatoid arthritis." [14]

	3	4 months	Pre- infection	Among Omicron cases, 3 mRNA doses pre-infection was associated with 9% fewer post-acute physical symptoms, compared to 2 mRNA doses pre-infection (IRR 0.91, 95%CI 0.88-0.94).	2 doses	Omicron	[23]
mRNA	3+	3 months	Pre- infection	Among Omicron cases, no significant difference in the mean number of PASC symptoms between those vaccinated with 3+ mRNA doses preinfection vs. unvaccinated individuals (mean 0.49 vs. 0.36, p=0.30).	Unvaccinated	Omicron	[25]
	1 or 2	3 months	Pre- infection	Among Omicron cases, those vaccinated with 1 or 2 mRNA doses pre-infection had a significantly higher mean number of PASC symptoms compared to those unvaccinated (mean 0.71 vs. 0.36, p=0.028).	Unvaccinated	Omicron	[25]

Appendix

Appendix 1: PRISMA Flow Chart

Figure 1. PRISMA flow chart for PASC published literature and preprints.

^{*}Preprints had already gone through title/abstract screening and had been tagged as relevant to PASC before being uploaded to this database

Appendix 2: Summary of study findings not included in synthesis tables of vaccine effectiveness

Reference	Key findings	ROBINS-I	Study design	Reason for exclusion from VE synthesis tables 1-8
Ayoubkhani [13]	A second ChAdOx1 dose post- infection was associated with a 8.7% decrease (95%CI -15.4 to -1.4%) in the odds of experiencing long covid (no OR reported). A second mRNA dose post- infection was associated with a 8.9% decrease (95%CI -17.6 to 0.7%) in the odds of experiencing long covid (no OR reported). A second ChAdOx1 or mRNA dose post-infection was associated with a 9.7% decrease (95%CI -16.5 to - 2.4%) in the odds of experiencing fatigue (aOR 0.903, 95%CI 0.835-0.976). A second ChAdOx1 or mRNA dose post-infection was not associated with a change in the odds of experiencing shortness of breath (aOR 1.012, 95%CI 0.921-1.111, p=0.81); muscle ache (aOR 0.948, 95%CI 0.860- 1.044, p=0.28); headache (aOR 0.91, 95%CI 0.819-1.010, p=0.08); loss of smell (aOR	Serious Serious	- Prospective cohort study Participants were infected before September 2021 in the UK (wildtype, Alpha, or Delta) An interrupted time series analysis was conducted to compare the odds of experiencing long covid in the same individuals before vs. after vaccination Final follow-up was median 267 days post-infection.	VE synthesis tables 1-8 - These data were excluded from VE synthesis tables due to comparison of the same individuals before vs. after vaccination (individual-level interrupted time series analysis).
	0.913, 95%CI 0.829-1.005, p=0.06); loss of taste (aOR 0.91, 95%CI 0.821-1.008, p=0.07); difficulty concentrating (aOR 0.954, 95%CI 0.866-1.052, p=0.35); memory loss or confusion (aOR 1.029, 95%CI 0.924-1.147, p=0.60); worry or anxiety (aOR 0.967, 95%CI 0.865-1.080, p=0.55).			
Jassat [20]	Among those vaccinated with 2 BNT doses or 1 Janssen dose, there was no significant difference in the risk of 1 or more persistent symptoms between individuals vaccinated after vs. before infection (aIRR 0.91, 95%CI 0.75-1.10, p=0.3413).	Serious	- Prospective cohort study Participants were infected between Nov 2020-Feb 2022 in South Africa (Beta, Delta, or Omicron) Final follow-up was 6 months post-infection.	- These data were excluded from VE synthesis tables due to comparison of individuals vaccinated after vs. before infection.

Spiliopoulos [23]	Among Omicron cases, 3 mRNA doses pre-infection was associated with a 18% lower score on the depression scale HADS-D (IRR 0.82, 95%CI 0.77-0.88); 16% lower score on the anxiety scale HADS-A (IRR 0.84, 95%CI 0.80-0.89); 5% lower score on the fatigue scale FAS (IRR 0.95, 95%CI 0.93-0.97); and a 9% lower score on the cognitive complaints scale COBRA (IRR 0.91, 95%CI 0.88-0.94), compared to 2 mRNA doses pre-infection.	Serious	- Prospective cohort study Cases were classified as Omicron infection based on variant predominance in Denmark (infected Dec 28, 2021-Jan 15, 2022) Final follow-up was 4 months post-infection.	- These data were excluded from VE synthesis tables due to continuous outcomes.
Brunvoll [24]	At 4-10 months post-infection, there was no significant difference in the Everyday Memory Questionnaire-13 (EMQ-13) mean score between those vaccinated with 2+ mRNA doses pre-infection vs. unvaccinated (mean 0.80 [95%CI 0.71, 0.88] vs. mean 0.90 [95%CI 0.84, 0.96], p= 0.69).	Serious	- Prospective cohort study Participants were infected after November 2020 in Norway (wildtype, Alpha, Delta, or Omicron) Final follow-up was median 110 days post-infection for vaccinated group, and median 293.5 days post-infection for unvaccinated.	- These data were excluded from VE synthesis tables due to continuous outcomes.

Appendix 3: Eligible PASC Outcome Domains

The following outcomes in each domain were taken directly from Table S4 in Supplementary Appendix 1 of the core outcome set for PASC [2].

Outcome Domain	Outcomes
Respiratory functioning, symptoms and	Sore throat
conditions	Sneezing
	New-onset Chronic obstructive pulmonary disease (COPD)
	Excessive sputum expectoration
	Nasal congestion
	Catarrh
	Wheezing
	Cough
	Lung fibrosis
	Pleurisy
	Pleural effusion
	Pain on breathing
	Pulmonary function abnormalities
	Hypoxaemia
	Respiratory failure
	Respiratory disease
	Bronchiectasis
F. Construction Con-	Asthma
Fatigue or exhaustion	
Pain	Diminos
	Dizziness Headache
	Stroke
	Autonomic dysfunction
	Tremors
	Seizures
	Taste disturbance
	Smell disturbance
	Bradykinesia
	Dysmetria
	Speech difficulty/dysarthria
	Numbness
	Guillain-Barré syndrome
	Abnormal reflex status
	Trigeminal neuralgia
	Neuralgia/neuropathy
	Frontal release signs
	Parkinsonism
	Problems with balance
	Encephalitis
	Brain physiology changes
Nervous system functioning, symptoms	Restless legs
and conditions	Abnormal muscle tone
	Confusion
Cognitive functioning, symptoms and	Concentration impairment
conditions	Memory impairment
	Depression
Montal functioning	Anxiety Post traumatic stress disorder (PTSD)
Mental functioning, symptoms and	Post-traumatic stress disorder (PTSD)
conditions	Acute stress disorder

	Mood shangs
	Mood change
	Obsessive-Compulsive Disorder (OCD)
	Behaviour change
	Thoughts of self-harm/suicide
	Risk to self and/or others
	Psychosis
	Traumatic bereavement
	Substance abuse
	Smoking habit
	Hallucinations
	Angina pectoris
	Acute coronary disease
	Heart rhythm issues
	Heart failure
	Palpitations
	Chest tightness
	Newly diagnosed hypertension
	Myocardial fibrosis
	Myo- or pericarditis
	Changes in cardiovascular fitness
Cardiovascular functioning, symptoms	Signal variations in the Electrocardiogram (ECG)
and conditions	High blood pressure
and conditions	i ligit blood pressure

First Author	Peer Review Status	Country	Funding (public, private, combined)	Study Design	Population	Study Period	Timing of Outcome follow up	Vaccine Type/ Brand	Total Sample Size	Total Vaccinated	Age (mean/ median), years	Reported measure of effect	Risk of Bias
Marra [21]	Preprint	Brazil	Combined	Case- control	HCWs	Mar 2020 – Jul 2022	180 days	CoronaV ac, ChAd, BNT, Ad26	7051	3853	Mean(SD) = 38.1 (8.7) for those with PASC; 37.2 (9.0) for those without PASC	Odds Ratio (OR)	Serious risk
Spiliopou los [23]	Preprint	Denmark	None	Prospe ctive cohort	General population	July 2021 - Jan 2022	4 months after testing positive for COVID	BNT, Moderna, Ad26, AZ	44,004	NR	Median(IQR)= 57 (46- 70) males, 62 (52-71) females	Risk Difference (RD). Raw data in the study was used to calculate crude OR and then VE.	Serious risk
Herman [18]	Publish ed	Indonesi a	Public	Case- control	General population	Jul 2021 - Dec 2021	90 days after COVID onset or diagnosis	inactivate d viral vaccine	923	168	Mean(SD) = 32.77 (10.4)	Odds Ratio (OR)	Critical risk
Brunvoll [24]	Publish ed	Norway	Public	Prospe ctive cohort	General population	Nov 2020 - NR	median 110.0 days (IQR 25.0) since COVID-19 for vaccinated; median 293.5 days (IQR 85.0) for unvaccinat ed	mRNA	1420	360	Mean(SD) = 48.3 (11.4) for vaccinated; 45.7 (12.3) for unvaccinate d	Odds Ratio (OR)	Serious risk
Jassat [26]	Publish ed	South Africa	Combined	Prospe ctive cohort	General population (including hospitalized and non- hospitalized for COVID)	Nov 2020 - Feb 2022	6 months	BNT, Ad26	3700	2537	Median(IQR) for hospitalized = 49(37-60); for non- hospitalized = 37(28-47)	Incident Risk Ratio (IRR)	Serious risk
Ballouz [17]	Preprint	Switzerla nd	Combined	Retrosp ective cohort	General population	Aug 2020 – Feb 2022	median 183 days (IQR 182- 186)	mRNA, Adenovir us vector	1350	NR	Median(IQR) = 48 (34- 63)	Odds Ratio (OR)	Serious risk
Kahlert [25]	Preprint	Switzerla nd	Combined	Prospe ctive cohort	HCWs	Aug 2020 - June 2022	median 3.1 months (IQR 2.6- 4.0)	BNT, mRNA	2912	2698	Median= 44	Mean number of symptoms	Serious risk
Ayoubkh ani (2) [12]	Publish ed	UK	Combined	Prospe ctive cohort	General population	Apr 2020 - Nov 2021	median 96 days (IQR 90-104) after infection for vaccinated ; median 98 days (IQR 89- 109) for	ChAd, Moderna, BNT	3090	3090	Mean(SD) = 49.0 (12.0)	Odds Ratio (OR)	Critical risk

							unvaccinat ed				
Ayoubkh ani [13]	Publish ed	UK	Combined	Prospe ctive cohort (interru pted time series analysi s)	General population	Feb 2021- Sep 2021	Median 67 days (IQR 20-99) after second dose, median 267 days (IQR 219- 431) after COVID infection	mRNA, ChAd	28,356	NR	Mean(SD)= 45.9 (13.6)
Taquet [15]	Publish ed	USA	Combined	Retrosp ective cohort	General population	Jan 2021 - Aug 2021	6 months	BNT, Moderna, Ad26	18958	9479	Mean(SD)= 57.0 (17.9)
Brannoc k [19]	Preprint	USA	NR	Retrosp ective cohort	General population	Aug 2021 - Jan 2022	120-300 days after infection	mRNA, viral vector vaccine	47752	26567	Mean= 48.17
loannou [16]	Publish ed	USA	Public	Retrosp ective cohort	Veterans	Feb 2020 - Dec 2021	8 to 12 months after COVID infection	BNT, Moderna	198,60 1	2447 (3.6%)	Mean(SD) = 60.4 (17.7)
Al-Aly [14]	Publish ed	USA	Combined	Retrosp ective cohort	Veterans	Jan 2021- Oct 2021	6 months	BNT, Moderna, Ad26	13,369, 073	33940	Mean = 66.63
Patel [22]	Publish ed	USA	Combined	Prospe ctive cohort	Patients with systemic autoimmune rheumatic diseases	Mar 2020 – Aug 2022	90 days	mRNA, Ad26	280	116	Mean(SD) = 53 (15)

Appendix 5. Critical Appraisal Process for Studies on Vaccination and PASC Outcomes

ROBINS-I Domain	Study characteristic that may introduce bias
ROBINS-I: Bias in selection of participants into study	Study design Method for confirming previous COVID infection
ROBINS-I: Bias in classification of interventions	Method for confirming vaccination
ROBINS-I: Bias due to confounding ROBINS-I: Bias in measurement of outcomes	 Accounting for non-immune period Accounting for calendar time Adjustment for prognostic factors Accounting for re-infections Accounting for period of time between vaccination and infection Detection of PASC in vaccinated vs. unvaccinated Systematic COVID testing
ROBINS-I: Bias due to deviations from intended interventions	Not applicable for vaccination as intervention
ROBINS-I: Bias due to missing data	Missing data in vaccinated vs. unvaccinated
ROBINS-I: Bias in selection of the reported result	Discrepancies in methods vs. results sections

ROBINS-I: Bias in selection of participants into study

Study design

Prospective cohort = low

Case-control/retrospective cohort/data-linkage = moderate

If any concerns about case-control/cohort/data-linkage = serious

Surveillance cohort = moderate

Surveillance cross-sectional or any cross-sectional or ecological = serious

Survey = critical

Method for confirming previous COVID infection

National or state or provincial registry/surveillance database, EMRs = low

Self-reported previous COVID infection without laboratory or clinical confirmation, for some or all participants = serious

ROBINS-I: Bias in classification of interventions

Method for confirming vaccination

Vaccine/immunization database/onsite vaccinations/prison or military records = low

Questionnaire with subset confirmed with registry/EHR = moderate

Self-report = serious

Not reported/estimated vaccine coverage = critical

ROBINS-I: Bias due to confounding

Accounting for non-immune period following vaccination (first 14 days after 2nd dose and first 7 days after any booster dose) *only applicable to those infected after vaccination

Clearly stated that infection occurred beyond non-immune period for last dose of vaccine = low

No clear statement about timing of infection post vaccination but at least 2 doses of vaccine administered = moderate

No statement about timing of infection post vaccination and only 1 dose of vaccine administered = serious

Accounting for calendar time

Use of time-varying statistics without explicit mention of adjustment for calendar time (e.g. results stratified by dominant variant wave) = moderate

Not taken into account but short time frame (e.g. ≤ 2 months) = serious

Not taken into account and time frame >2 months = critical

Adjustment for prognostic factors

No or insufficient adjustment for occupation (number of tests as surrogate for exposure risk) = moderate – occupation not relevant for LTCF

No or insufficient adjustment for socioeconomic factors (neighborhood or income as surrogate; municipality= serious because could include all income brackets), race, ethnicity = serious

No or insufficient adjustment for age or chronic medical conditions/comorbidities (any study population) = critical

Accounting for re-infections

Accounted for number of previous COVID infections = low

Not accounted for/unclear that re-infections were considered = serious

ROBINS-I: Bias in measurement of outcomes

Detection of PASC in vaccinated vs. unvaccinated

Symptoms assessed prospectively using standardized report forms with clear statement or criteria that symptoms only began after infection = low

Symptoms assessed retrospectively using EHRs and pre-specified checklist of PASC symptoms, and recorded as new after infection = moderate

Symptoms assessed at a PASC clinic = moderate

No method of verifying symptoms were new after infection, or symptoms were reported before infection = critical

One group assessed by a different method compared to other group (e.g. one group assessed by self-report survey and other group assessed at clinic/by doctor) = critical

Systematic COVID testing

Vaccinated and unvaccinated systematically tested for COVID and found to be negative at time of PASC assessment = low

Vaccinated and unvaccinated not tested at time of PASC assessment = serious

One group systematically tested for COVID and the other is not, or participants found to be positive with COVID at time of PASC assessment = critical

ROBINS-I: Bias due to missing data

Missing data in vaccinated vs. unvaccinated

Outcome data is available for all/nearly all participants (e.g. 90-95%); or the proportion of missing participants in vaccinated vs. unvaccinated groups is similar, and reasons for missing participants are similar = low

Proportion of missing participants in vaccinated vs. unvaccinated groups differs substantially, or reasons for missing differ substantially; and missing data was not sufficiently addressed through analysis = serious

Missing data was not/could not be addressed through analysis = critical

ROBINS-I: Bias in selection of the reported result

Discrepancies in methods vs. results sections

All measurements for a PASC outcome described in the methods are reported in results; all analyses of the vaccination-PASC relationship (e.g. unadjusted and adjusted models) described in the methods are reported in results; and all subgroups described in the methods are reported in results = low

PASC outcomes are defined in different ways in the methods and results sections; or not all analyses of the vaccination-PASC relationship described in methods are reported in results; or not all subgroups described in methods are reported in results = serious

Analyses of the vaccination-PASC relationship described in methods but not reported in results are likely to produce substantially different estimates from the reported estimates = critical
